Booster Selection Bulletin

Booster Selection Bulletin

SYSTEM SIZING CRITERIA

STEP A - TOTAL PUMPING HEAD

Total pumping head in a booster system is made up of five components (shown on figure 4) as follows:

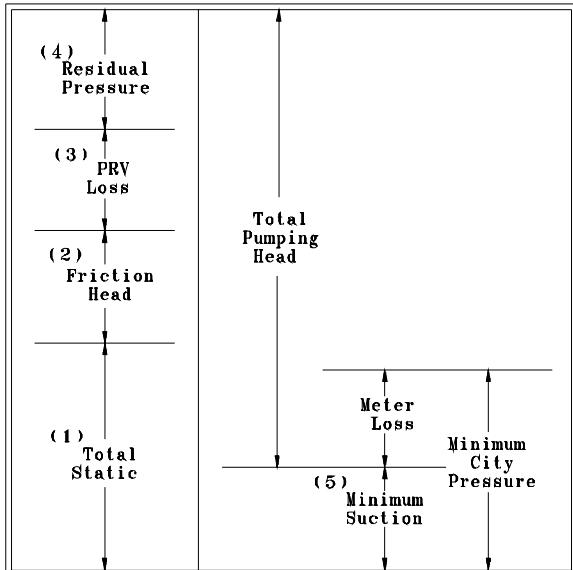

- 1) *Total Static Height* - i.e. The vertical distance in feet from the street main to the highest fixture. This can be obtained from the building plans but will normally be approximately ten times the number of floors, allowing 10 ft. between floors.
- 2) *Friction Head* - i.e. The friction loss in feet through all pipes and fittings on the suction and discharge. This component can be accurately calculated by reference to pipe friction data. More simply, the friction loss in a typical booster system will amount to approximately to 10% of the building static height.
- 3) *PRV Loss*. An average pressure drop of 5 psi should be used to ensure good water velocities through the pressure reducing valve the head loss should be limited to a maximum of 10 psi, or approximately 20 ft.
- 4) *Residual Pressure* - i.e. The pressure required at the highest fixture, pressure in feet. This will depend on the type of fixture, but a fairly typical figure is 40 psi.
- 5) *Minimum Suction Pressure* - i.e. This is the minimum pressure at the building side of the meter, expressed in feet -i.e. The minimum city pressure minus the pressure drop through the meter. If the meter loss is not readily available, allow approximately 10 psi.

$$\text{Total Pumping Head} = (1) + (2) + (3) + (4) - (5)$$

The head calculation for a typical booster system is shown below:

(1) Total Static Height	300 ft.
(2) Friction Head (10% of Static)	30 ft.
(3) PRV Loss (5 PSI)	12 ft.
(4) Residual Pressure (40 psi)	<u>92 ft.</u>
(1) + (2) + (3) + (4)	434 ft.
(5) Minimum Suction Pressure (60 psi)	<u>138 ft.</u>
	Total Pumping Head 298 ft.

Figure 4. TOTAL PUMPING HEAD REPRESENTATION

STEP B - TOTAL PUMPING CAPACITY

The estimation of total pumping capacity of a booster system must take into consideration such factors as the size of the building and the living habits of its occupants. These factors, particularly the human element, cannot be covered by engineering formulas, and it becomes necessary to rely on operating data and records compiled over the years by various users, manufacturers and trade associations.

In the days of roof tanks and hydro-pneumatic systems, an accurate estimation of water demand was not too important, since the booster pumps merely operated when required to maintain the pre-determined levels in the storage tank. Such is not the case with "tankless" systems, however, since the rate of pumping exactly matches the rate of water usage in the building. This has resulted in a more critical appraisal of the methods used to determine water demand, and it is generally agreed that most of the existing data is much too conservative.

The "Fixture Unit" method is the one most commonly employed, and this is the basis of water demand data published by ASPE, ASHRAE and also by many pump manufacturers.

Each different type of fixture is given a demand weight in fixture units and total demand is obtained by calculating the total number of fixture units in a building and converting that number to a total GPM by referring table 2 which shows the relationship of GPM to total fixture units.

Special Services - It must be emphasized that the capacity charts show fixture demand only. Special requirements such as air-conditioning apparatus, commercial laundries, process equipment, blueprint machines, swimming pools, hose connections, etc. must be estimated separately and added to the fixture demand to obtain total demand.

Existing Buildings - If the booster system is being installed in an existing building there is a possibility that the water requirements may have been determined by a meter. In such a case, the total pumping capacity should be three (3) times the average metered demand to allow for peak periods.

Occupancy - Capacity ratings are based on the assumption that an equal number of men and women are to be accommodated. Where the occupancy is predominantly female, increase the total pumping capacity by 15%.

Laundries - In the case of hotels and hospitals, where a laundry is operated in connection with the building, increase the total pumping capacity by 10% *only* when scheduled for operation at low water demand periods.

1995 Change to the National Standard Plumbing Code adopted at NSPC Public Hearing - August 1994

Table 2 FIXTURE UNIT TABLE

NOTES:

1. A Bathroom Group for the purposes of this table consists of not more than one water closet, up to two lavatories, and either one bathtub or one shower.
2. "Other than Dwelling Units" applies to business, commercial, industrial and assembly occupancies other than those defined under "Heavy use Assembly". Included are the public areas in hotels, motels and multi-dwelling buildings.
3. "Heavy use Assembly" applies to toilet facilities in occupancies which place heavy but intermittent, time based demands on the water supply system, such as; schools, stadiums, race courses, transportation terminals, theaters and similar occupancies.
4. For fixtures or supply conditions likely to impose a continuous flow demand, determine the required flow in gallons per minute (GPM) and add it separately to the demand (GPM) for the distribution system or portion thereof.

WATER DEMAND TABLE		
Fixture Units	Flush Tanks Demand-GPM	Flush Valves Demand-GPM
100	44	68
200	65	91

TABLE 3. TOTAL FIXTURE UNITS to GPM

PUMP SIZING

After the total head and maximum demand have been determined, it is necessary to establish the number of pumps and pump sizing required to obtain the best overall pumping arrangement. In this respect, it should be noted that while the whole system has to be capable of handling maximum demand, the average demand will be considerably less. For example, in apartment buildings and office buildings it will be found that for approximately 75% of the time the actual demand will be 30% or less of peak demand. This consideration makes it economical to resort to split pumping, with the lead pump (or pumps) sized for low demand requirements.

Recommended Capacity Splits

a) **Two -Pump 33%/67%**

This energy saving arrangement due to the smaller lead pump finds application in residential and office buildings up to a maximum demand of approximately 300 GPM.

b) **Two-Pump 50%/50%**

This arrangement is also used in small buildings. Note that it provides 50% standby in the event of failure of any one pump and also permits alternation to equalize wear.

c) **Three-Pump 33%/33%/33%**

Minimum standby capacity is 66%, and the three pumps are alternated to share the demand load and provide equal wear.

d) **Three-Pump 20%/40%/40%**

Smaller lead pump provides energy savings during long periods of low demand. The two equal lag pumps allow for alternation and minimum standby capacity of 60% if any one pump fails.

STEP C - CAPACITY SPLIT

(See recommendations on pump sizing)

System Type	Split		
	%	%	%
DUPLEX			
TRIPLEX			
	P1 GPM	P2 GPM	P3 GPM
PUMP CAPACITY (TOTAL CAPACITY x % SPLIT)			

6 _____

STEP D - BOOSTER PUMP SELECTION

1) Record the value of the Pumping Head required (Step A) and the Pumping Capacity obtained (Step B).

2) Based on the capacity split chosen, i.e.:

Duplex: 33%-67%, Triplex: 20%-40%-40%

or

Duplex: 50%-50%, Triplex: 33%-33%-33%

Choose the selection tables accordingly.

3) Select the pumps according to the system capacity determined and the pump boost pressure calculated.

Tables are available for Vertical In-Line pumps or End suction Pumps. Series 6500 & 6600 are end suction, Series 6700 are Vertical In-Line. Choose the pumps that best fit your requirements (i.e.: HP, arrangement, pump type)

Example: Required Pumping Head: 50 PSI
Required System Capacity: 100 GPM
System Capacity Split: Duplex - 33%-67%

From the 6500 & 6600 table the selection is:

P1 : 1.5x1x6 - 5 HP, P2: 3x1.5x6 - 7.5 HP

(this selection can be used for capacities up to 150 gpm)

From the 6700 table the selection is:

P1: 1.5x1.5x6 - 5 HP, P2: 2x2x6 - 7.5 HP

(this selection can be used for capacities up to 150 gpm)

Both units have the same nominal horsepower rating, decision will be based on pump type or Booster piping arrangement layout and footprint..

	Model	Pump Size	HP
P1			
P2			
P3			

STEP E - BOOSTER MODEL DESIGNATION

Having chosen the desired model series 6500, 6600 or 6700 and knowing the system type is either simplex duplex or triplex the complete system model designation can be given.
